

Confidence Interval Estimation

Types of Estimates

- Point Estimate
 - A single number used to estimate an unknown population parameter
- Interval Estimate
 - A range of values used to estimate a population parameter
 - Characteristics
 - Better idea of reliability of estimate
 - Decision making is facilitated

Point Estimates

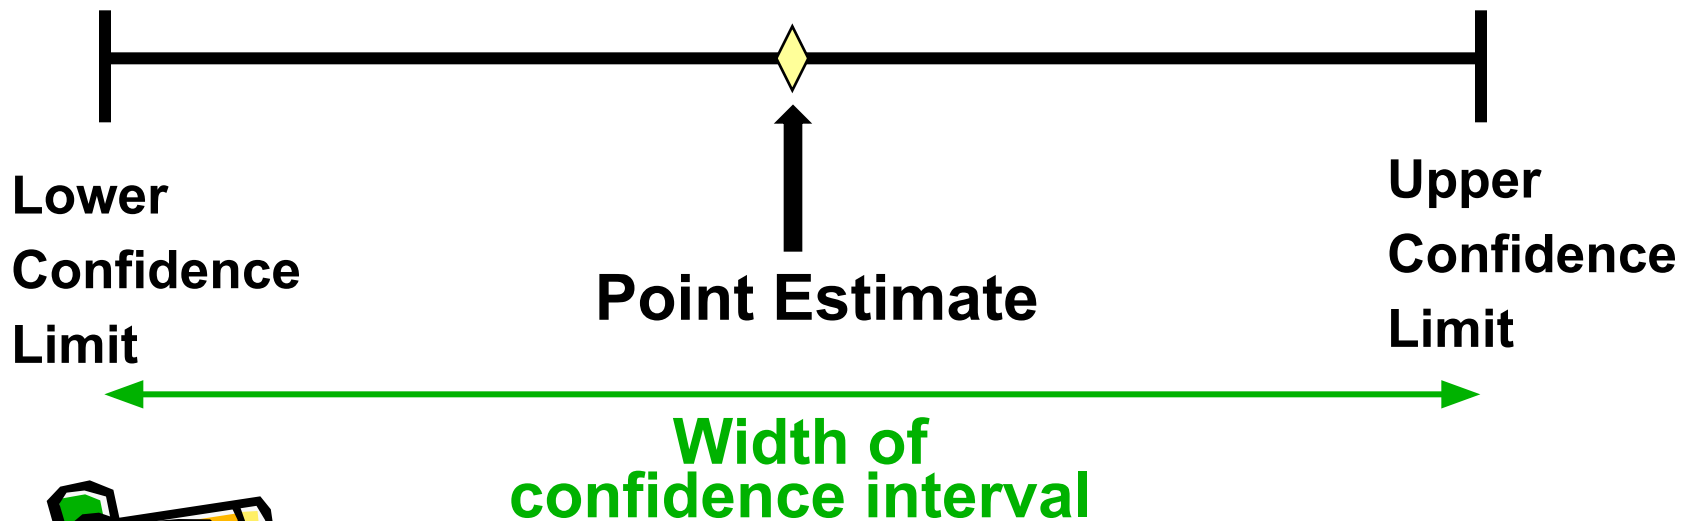

Estimate Population Parameters ...	with Sample Statistics
Mean	μ \bar{X}
Standard deviation	σ S
Variance	σ^2 S^2
Difference	$\mu_1 - \mu_2$ $\bar{X}_1 - \bar{X}_2$

Point and Interval Estimates

- A **point estimate** is a single number,
- a **confidence interval** provides additional information about variability

Confidence Interval Estimate

- An interval gives a **range** of values:
 - Takes into consideration the variation in sample statistics from sample to sample
 - Based on observation from 1 sample
 - Gives information about closeness to unknown population parameters
 - Stated in terms of level of confidence
 - Can never be 100% confident

Confidence Level, $(1-\alpha)$

- Suppose confidence level $\gamma = 95\%$
- Also written $\gamma = (1 - \alpha) = .95$
- Where α is the risk of being wrong
- A relative frequency interpretation:
 - In the long run, 95% of all the confidence intervals that can be constructed will contain the unknown parameter
- A specific interval either will contain or will not contain the true parameter
 - No probability involved in a specific interval

Estimation Process

Random Sample

Population
(mean, μ , is
unknown)

Sample

Mean
 $\bar{x} = 50$

I am 95%
confident that
 μ is between
40 & 60.

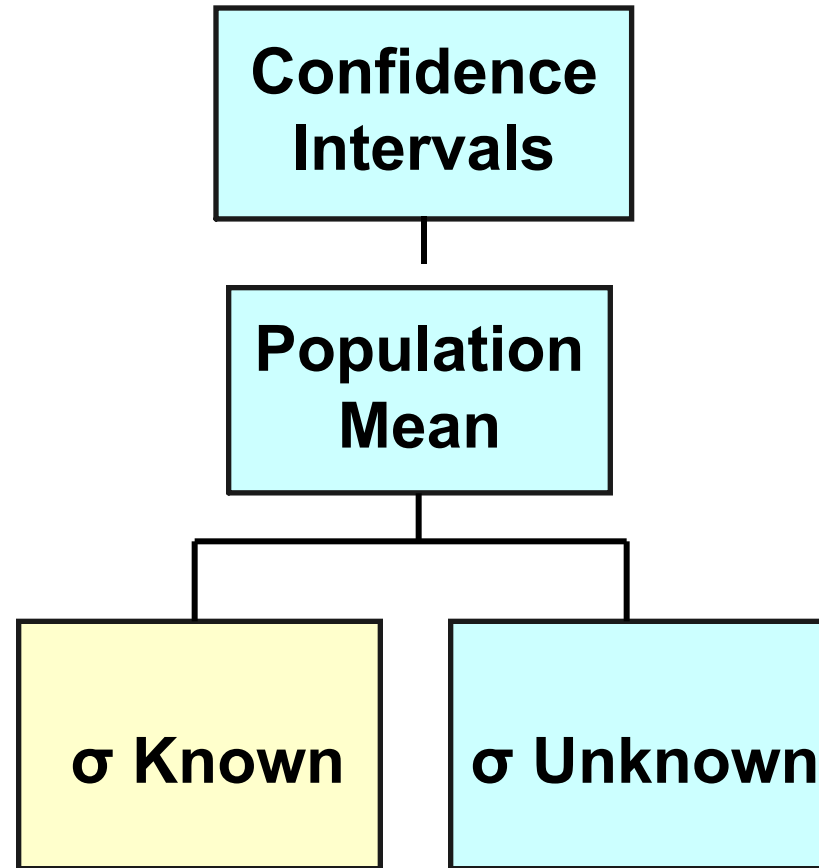

General Formula

- The general formula for all confidence intervals is:

Point Estimate \pm (Critical Value)(Standard Error)

Confidence Intervals

Confidence Interval for μ (σ Known)

- Assumptions
 - Population standard deviation σ is known
 - Population is normally distributed
 - If population is not normal, use large sample
- Confidence interval estimate for μ

$$\bar{x} \pm z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$

Critical Value

Standard error

Finding the Critical Value

Confidence Level γ	Confidence Coefficient, $\gamma = 1 - \alpha$	z value, $Z_{\alpha/2}$
80%	.80	1.28
90%	.90	1.645
95%	.95	1.96
98%	.98	2.33
99%	.99	2.57
99.8%	.998	3.08
99.9%	.999	3.27

Finding the Critical Value

- Consider a 95% confidence interval:

Margin of Error

- **Margin of Error (e):** the amount added and subtracted to the point estimate to form the confidence interval

Example: Margin of error for estimating μ , σ known:

$$\bar{x} \pm z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$

$$e = z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$

Factors Affecting Margin of Error

$$e = z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$

Intervals Extend from

$$\bar{X} - Z\sigma_{\bar{X}} \text{ to } \bar{X} + Z\sigma_{\bar{X}}$$

• Data variation, σ :

e ↓ as σ ↓

• Sample size, n :

e ↓ as n ↑

• Level of confidence, $1 - \alpha$:

e ↓ if $\gamma = 1 - \alpha$ ↓

Example

A sample of 11 circuits from a large normal population has a mean resistance of 2.20 ohms. We know from past testing that the population standard deviation is .35 ohms.

Determine a 95% confidence interval for the true mean resistance of the population.

Solution -

$$\begin{aligned} & \bar{x} \pm z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \\ &= 2.20 \pm 1.96 (.35/\sqrt{11}) \\ &= 2.20 \pm .2068 \\ & (1.9932 \ ; \ 2.4068) \end{aligned}$$

To get a Z value use the **NORMSINV** function with

$$p = \gamma + \alpha/2$$

for 95% confidence use 0.975

$$= \text{NORMSINV}(0,975)$$

$$= \text{NORM.S.INV}(0,975)$$

Result = 1.96

Interpretation

- We are $\gamma=95\%$ confident that the true mean resistance is between 1.9932 and 2.4068 ohms

Confidence Interval for μ (σ Unknown)

- If the population standard deviation is **unknown**, we can substitute the sample standard deviation, **s** as an estimate

In these case the **t-distribution** is used instead of the normal distribution

Student's t Distribution

Note: $t \rightarrow$ Normal as n increases

Confidence Interval for μ (σ Unknown)

- Assumptions

- Population standard deviation is unknown
- Population is not highly skewed
- Population is normally distributed or the sample size is large (>30)

- Use Student's t Distribution

- Confidence Interval Estimate:

$$\bar{x} \pm t_{\gamma} \frac{s}{\sqrt{n}}$$

- where t is the critical value of the **t-distribution** with $n-1$ degrees of freedom and an area of $\alpha/2$ in each tail)

Define t_γ from equation

$$P(|T| < t_\gamma) = \gamma$$

γ - Confidence Coefficient.

t_γ - obtain with using Excel function **TINV**.

$$\begin{aligned} t_\gamma &= \text{TINV}(1 - \gamma; n-1) \\ &= \text{T.INV.2T}(1 - \gamma; n-1) \end{aligned}$$

Example

A random sample of $n = 25$ has $\bar{X} = 50$ and $S = 8$. Form 95% confidence interval for μ

- degrees of freedom = $n - 1 = 24$,
- $\gamma = 0,95$.

To get a **t - value** use the **TINV** function.
The value of **alpha** **=(1 - confidence)** and **n-1** degrees of freedom are the inputs needed.

For **95%** confidence use **alpha =0.05** and for a sample size of **25** use **24** df

$$t_{\gamma} = \text{TINV}(0,05; 24) = 2,0639$$

$$t_{\gamma} = \text{T.INV.2T}(0,05;24) = 2,0639$$

$$\bar{X} \pm t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} = 50 \pm (2.0639) \frac{8}{\sqrt{25}}$$

$$46.698 \dots \mu \dots 53.302$$
$$46.698 \leq \mu \leq 53.302$$

Confidence Interval on the Variance and Standard Deviation of a Normal Distribution

Definition

Let X_1, X_2, \dots, X_n be a random sample from a normal distribution with mean μ and variance σ^2 , and let S^2 be the sample variance. Then the random variable

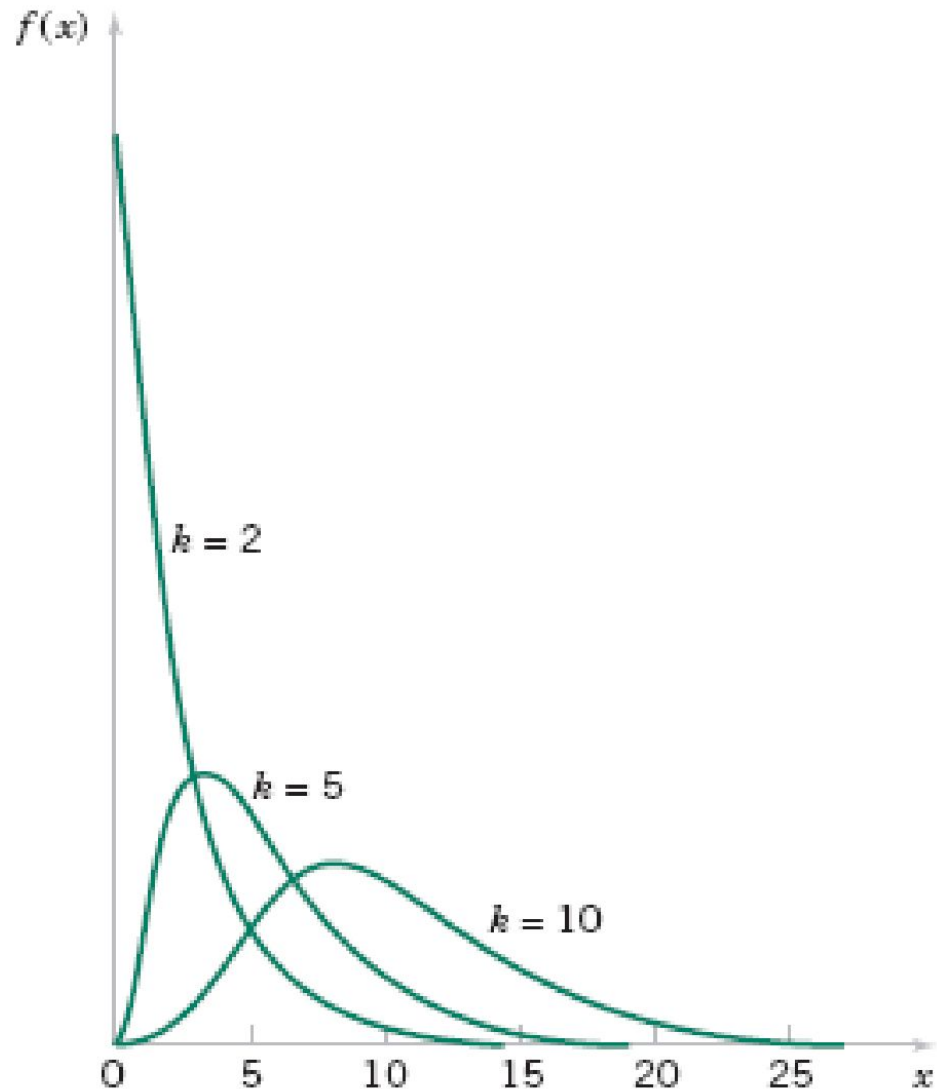

$$X^2 = \frac{(n - 1) S^2}{\sigma^2} \quad (8-19)$$

has a chi-square (χ^2) distribution with $n - 1$ degrees of freedom.

Confidence Interval on the Variance and Standard Deviation of a Normal Distribution

Probability density functions of several χ^2 distributions.

The confidence interval is chosen so that the area under the lower tail will equal area under upper tail, i.e. the probabilities are equal of hitting the right and left area.

Confidence Interval on the Variance and Standard Deviation of a Normal Distribution

$$P\left(\frac{\sqrt{n-1}S}{\sqrt{\chi_2^2}} < \sigma < \frac{\sqrt{n-1}S}{\sqrt{\chi_1^2}}\right) = \gamma$$

where χ_1^2 is the critical value of the χ^2 distribution with $n-1$ degrees of freedom and $a_1 = (1 + \gamma)/2$;

χ_2^2 is the critical value of the χ^2 distribution with $n-1$ d.f. and $a_2 = (1 - \gamma)/2$.

We can use χ^2 -Table for solving next equation

$$P\left(\chi^2 \geq \chi_q^2\right) = q$$

Or EXCEL function *CHIINV* ($q; n-1$),
=CHISQ.INV.RT($q;n-1$).

EXAMPLE

According to the 20 measurements found standard deviation $S = 0,12$. Find **precision** measurements with reliability **0.98**.

With using *CHIINV* ($q; n-1$) we obtain χ_1^2 i χ_2^2 .
For degrees of freedom $n - 1 = 19$ and
probability $\alpha_2 = (1 - 0,98) / 2 = 0,01$ define

$$\chi_2^2 = 36,2,$$

after that for $n - 1 = 19$ and probability
 $\alpha_1 = (1 + 0,98) / 2 = 0,99$ define $\chi_1^2 = 7,63$.

$$\chi_2^2 = \text{CHIINV}(0,01; 19) = 36,2 ;$$
$$= \text{CHISQ.INV.RT}(0,01; 19).$$

$$\chi_1^2 = \text{CHIINV}(0,99; 19) = 7,63.$$
$$= \text{CHISQ.INV.RT}(0,01; 19).$$

calculate

$$\frac{\sqrt{20-1} * 0,12}{\sqrt{36,2}} = \frac{4,36 * 0,12}{6,06} = 0,09; \quad \frac{\sqrt{20-1} * 0,12}{\sqrt{7,63}} = \frac{4,36 * 0,12}{2,76} = 0,19.$$

Confidence Interval for σ is $(0,09;0,19)$.
