- ✓ Replace all off-chip passive elements with MEMS resonators & filters ⇒ chip-scale integration & improved performance

Индуктивность Microinductor

(a)

(b)

The PARC inductor: (a) scanning-electron micrograph (SEM) of a five-turn solenoid inductor (the locations of the sides of the turns before release are visible); and (b) SEM close up of the tops of the turns where the metal from each side meets, showing the interlocked ends. The etch holes have been filled with copper.

Индуктивность - последовательность производства НЭМС Fabrication of microinductor

1. Deposit Cu ground plane. Deposit and pattern dielectric.
Sputter sacrificial metal and Au/MoCr/Au stack with stress gradient in MoCr.
Pattern metal with photoresist and etch.

2. Etch sacrificial layer to release MoCr film, which curls slightly.
Heat to relax photoresist. Au/MoCr/Au stack curls completely.

3. Strip photoresist.
Electroplate Au/MoCr/Au with copper.

воздух $Q < 50$

Resonant frequency:

$$f_r = \frac{1}{2\pi} \sqrt{\frac{k_{total}}{m_p + 0.25m_c + 0.34m_b}}$$

k_{total} = System spring constant

m_p = Mass of shuttle

m_c = Mass of connector

m_b = Mass of spring beams

$$k = E t (w/L)^3$$

$$E = 160 \text{ GPa}$$

$$t = 2 \text{ } \mu\text{m}$$

$$w = 2 \text{ } \mu\text{m}$$

$$L = 33 \text{ } \mu\text{m}$$

$$m = 5.7 \cdot 10^{-11} \text{ kg}$$

$$f = 190 \text{ kHz}$$

Illustration of a micromachined folded-beam comb-drive resonator. The left comb drive actuates the device at a variable frequency ω . The right capacitive-sense-comb structure measures the corresponding displacement by turning the varying capacitance into a current, which generates a voltage across the output resistor. There is a peak in displacement, current, and output voltage at the resonant frequency.

Высокочастотный резонатор с термокомпенсацией

Resonator with thermal compensation

(a)

(b)

Illustration of the compensation scheme to reduce sensitivity in a resonant structure to temperature. A voltage applied to a top metal electrode modifies through electrostatic attraction the effective spring constant of the resonant beam. Temperature changes cause the metal electrode to move relative to the polysilicon resonant beam, thus changing the gap between the two layers. This reduces the electrically induced spring constant opposing the mechanical spring while the mechanical spring constant itself is falling, resulting in their combination varying much less with temperature. (a) Perspective view of the structure, and (b) scanning electron micrograph of the device. (Courtesy of: Discera, Inc., Ann Arbor, Michigan, USA.)

.Регуляторы потоков. Microvalves

Области применения:

- Electronic flow regulation of refrigerant for increased energy savings;
- Electronically programmable gas cooking stoves;
- Electronically programmable pressure regulators for gas cylinders;
- Accurate mass flow controllers for high-purity gas delivery systems;
- Accurate drug delivery systems;
- Control of fluid flow in portable biochemical analysis systems;
- Portable gas chromatography systems;
- Proportional control for electrohydraulic braking (EHB) systems.

Нормально-открытый регулятор потока Normally open microvalve

Illustration of a normally open valve from Redwood Microsystems, Ca. Heating of a control liquid sealed inside a cavity causes a thin silicon diaphragm to flex and block the flow through the outlet orifice. The inlet port is not shown.

The flow rate ranges from 0.1 sccm up to 1,500 sccm. The maximum inlet supply pressure is 690 kPa, the switching time is typically 0.5s, and the corresponding average power consumption is 500 mW.

Нормально-закрытый регулятор потока

Normally closed microvalve

Illustration of the basic operating mechanism of a normally closed micromachined valve from Redwood Microsystems. (a) The upper stage of the valve normally blocks fluid flow through the outlet orifice. The inlet orifice is not shown. (b) Heating of the Fluorinert liquid sealed inside a cavity flexes a thin silicon diaphragm which in turn causes a mechanical lever to lift the valve plug.

Ограничения регулятора потока с термо-пневматическим приводом

- Утечка тепла **Leak of heat**

Микроклапан с приводом из металла с памятью формы

Normally closed valve with shape-memory-alloy actuator

Assembly of the micromachined, normally closed valve with TiNi alloy actuator. The beryllium-copper spring pushes a sapphire ball against the silicon poppet to close the flow orifice. Resistive heating of the TiNi spring above its transition temperature causes it to recover its original flat (undeflected) shape. The actuation pulls the poppet away from the orifice, hence permitting fluid flow. (After: A. D. Johnson, TiNi Alloy Company of San Leandro, California.)

Микроклапан – последовательность изготовления привода Normally closed valve with TiN actuator – production steps

The valve consumes less than 200 mW and switches on in about 10 ms and off in about 15 ms. The maximum gas flow rate and inlet pressure are 1,000 sccm and 690 kPa (100 psig), respectively. The valve measures 8 mm × 5 mm × 2 mm and is assembled inside a plastic package. The list price for one valve is about \$200.

Микронасос Місрорупп

Illustration of a cutout of a silicon micropump from the Fraunhofer Institute for Solid State Technology of Munich, Germany. The overall device measures $7 \times 7 \times 2 \text{ mm}^3$. The electrostatic actuation of a thin diaphragm modulates the volume inside a chamber. An increase in volume draws liquid through the inlet check valve. Relaxation of the diaphragm expels the liquid through the outlet check valve. The pump rate initially rises with frequency and reaches a peak flow rate of $800 \text{ } \mu\text{l}/\text{min}$ at 1 kHz .

Микронасос - последовательность производства НЭМС

Микрожидкостные системы Microfluidic systems

Смешивание в микроканалах Laminar flow and mixing

Плотность density	$\rho = 1 \text{ g/cm}$
Вязкость viscosity	$\mu = 0.01 \text{ g/(cm s)}$
Диаметр трубы diameter	$d = 30 \text{ }\mu\text{m}$
Скорость потока flow rate	$v = 1 \text{ mm/s}$
Число Рейнолдса Reynolds number	$R = \rho v d / \mu = 0.03$
Критическое Critical	$R_c = 2300$

Example of the use of laminar flow in microfluidics: In the Cell LabChip from Agilent Technologies of Palo Alto, California, the flow of cells tagged with a fluorescent dye is pushed to one side of the channel. Individual cells are detected when they fluoresce.

Смешивание в микроканалах Mixing in microchannels

Very low Reynolds numbers = extremely laminar flow.

Анализ ДНК - Lab on a Chip DNA analysis

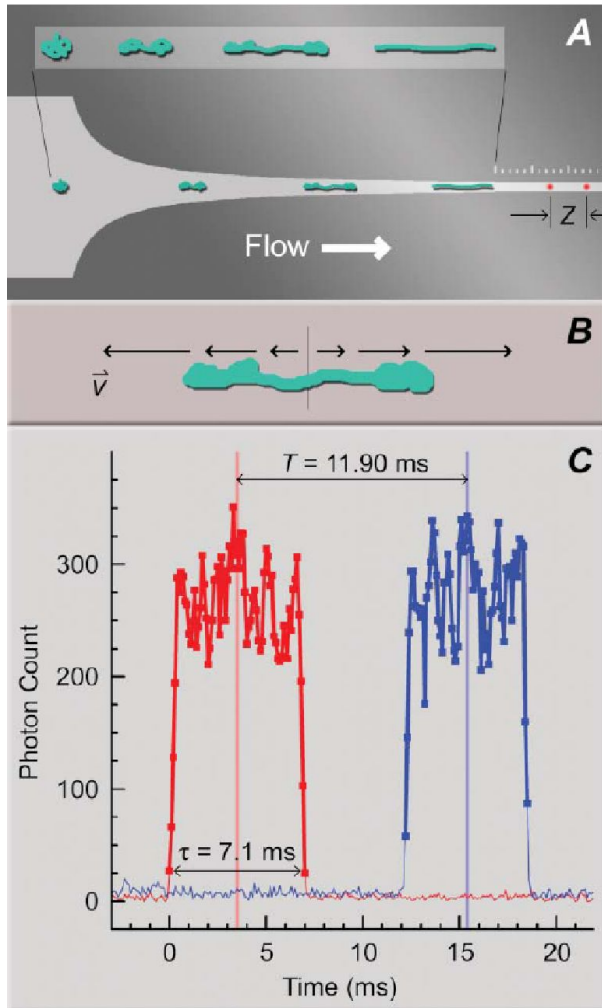

3'CAGTACGTCCAGCTGAGAC5'...

Bar code

Schematic of the microfluidic device. The device incorporates a two-dimensional, hydrodynamic flow focusing design for stretching individual I-phage DNA molecules. The sample is inserted into the DNA port (left side) along with 1X TE buffer into each of the sheath flow ports (top, bottom). Sample flow is from left to right. Inset: image of the laser spot positioned in the backlit microfluidic channel. The microfluidic channel is 5 mm wide in the interrogation region highlighted by the alignment fiducials on either side of the channel. Bar represents 25 mm. (Krogmeier, 2007)

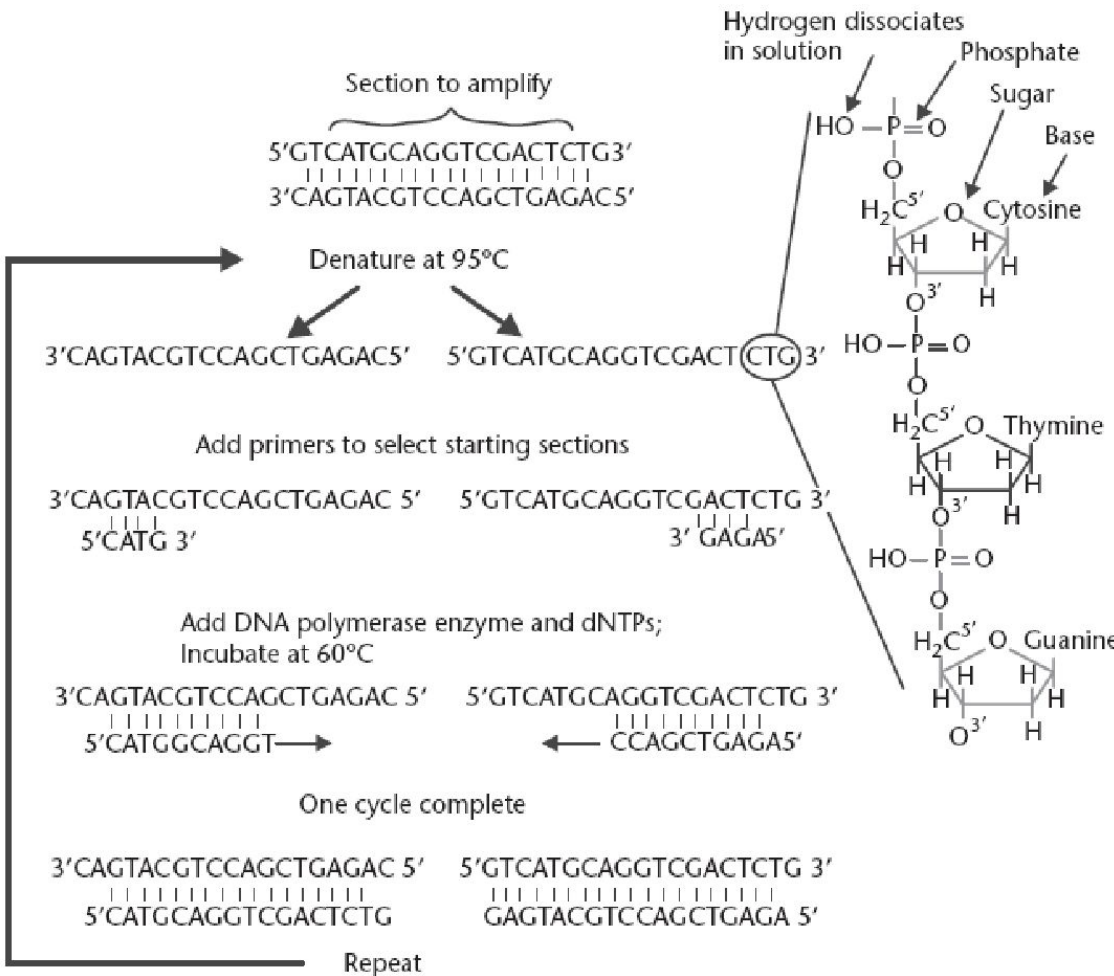

Анализ ДНК

Two-spot system for interrogating DNA conformations after stretching in mixed microflows. (A) CAD drawing of a funnel for high strain rate flows similar to those used in this study (constant strain rate design, $w_i = 50$ mm, $w_f = 2.5$ mm, $IF = 125$ mm), with a superimposed cartoon of DNA responding to the elongational component of the flow. The inset is provided for clarity. The constant width exit channel begins at the first tick mark on the ruler etched above the funnel (10 mm and 2 mm between major and minor tick marks, respectively). The two confocal spots for DNA fluorescence detection (red spots in the exit channel), separated by a distance, Z , are aligned at one contour length of the longest polymer in a mixture away from the end of the funnel. (B) Cartoon of DNA stretching in a pure elongational flow with a strong velocity gradient (equivalently, strain rate) along the polymer. (C) Example single DNA molecule detection event. Two similar fluorescence bursts from the separate confocal detection spots (red and blue traces for the first and second spots away from the funnel, respectively), with CMs marked as vertical lines, were separated by time T , indicating DNA velocity. Thick lines with symbols denote the contiguous region above a threshold value. The burst duration, t , reveals the length of the molecule in the projection of flow. $Z = 28$ mm for this example.

Синтез ДНК DNA synthesis

Twisted double-helix structure of DNA

Polymerase chain reaction (PCR). Denaturing of the starting DNA template at 95°C yields two strands, each containing all of the necessary information to form a complementary replica. The addition of primers defines the starting point for replication. At 60°C, the DNA polymerase enzyme catalyzes the reconstruction of the complementary DNA strand from an ample supply of nucleotides (dNTPs). The reconstruction always proceeds in the 5'→3' direction. The cycle ends with copies of two portions of the helices, in addition to the starting template. The cycle is then repeated. The exploded view of three nucleotides (CTG) in the denatured template shows their chemical composition, including the 3'-hydroxyl and 5'-phosphate groups.

Цепная реакция полимеразы в МЭМС Polymerase chain reaction in MEMS

Illustrations of (a) the front side, and (b) the back side of an early micromachined silicon PCR chamber. A polysilicon heater on a silicon nitride membrane cycles the solution between the denaturing and incubation temperatures of PCR.

Электрофорезная сортировка ДНК

Electrophoresis system for DNA separation

Illustration of the fluid injection and separation steps in a miniature DNA electrophoresis system. An applied electric field electrophoretically pumps the fluid molecules from port 3 to port 1 during the injection step. Another applied voltage between ports 2 and 4 initiates the electrophoretic separation of the DNA molecules. The smearing of the fluid plug in the separation channel is schematically illustrated. The capillary channels have a typical cross section of $8 \times 50 \mu\text{m}^2$. The separation capillary is 3.5 cm long.

Микроэлектроды Microelectrode array

Cross section of a microelectrode array showing two different metals for the electrodes and for the bond pads. The schematic also illustrates a basic electrical equivalent circuit that emphasizes the capacitive behavior of a microelectrode. The silicon substrate and the silicon dioxide dielectric layer may be substituted by an insulating glass substrate.

Анализ ДНК DNA analysis

МАССИВ МИКРОЭЛЕКТРОДОВ

Illustration of the Nanogen electronic addressing and detection schemes. (a) A positive voltage attracts DNA capture probes to biased microelectrodes. Negatively biased electrodes remain clear of DNA. Repetition of the cycle in different solutions with appropriate electrode biasing sequentially builds an array of individually distinct sites of DNA capture probes that differ by their sequence of nucleotides. (b) A DNA fragment with unknown sequence hybridizes with a DNA capture probe with a complementary sequence. Fluorescence microscopy reveals the hybridized site and, consequently, the unknown sequence.

Синтез массивов ДНК DNA synthesis

1. Coat substrate with bonding molecules and protection group

2. Expose UV light through mask to deprotect exposed area

3. Flush with solution containing one nucleotide (e.g., A)

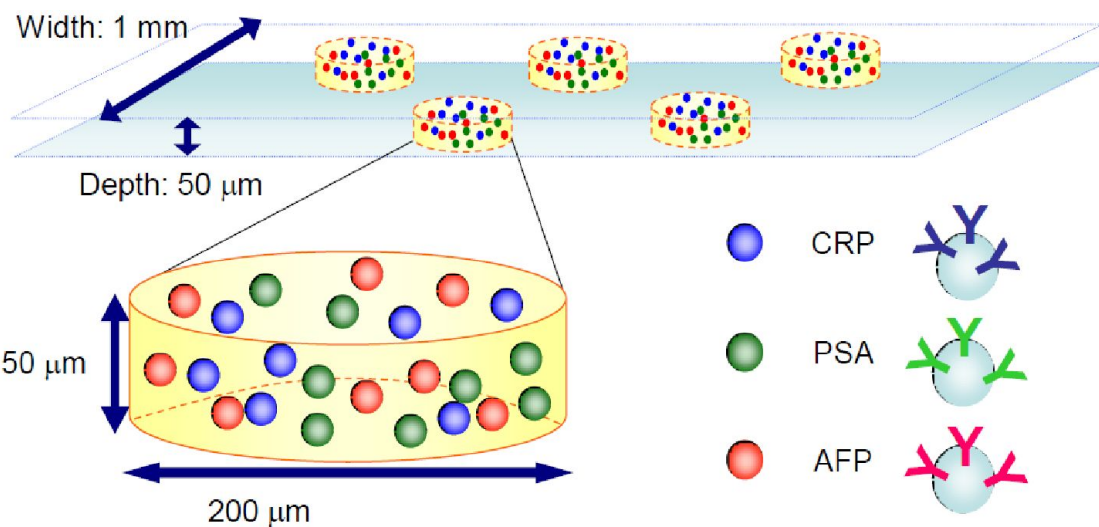

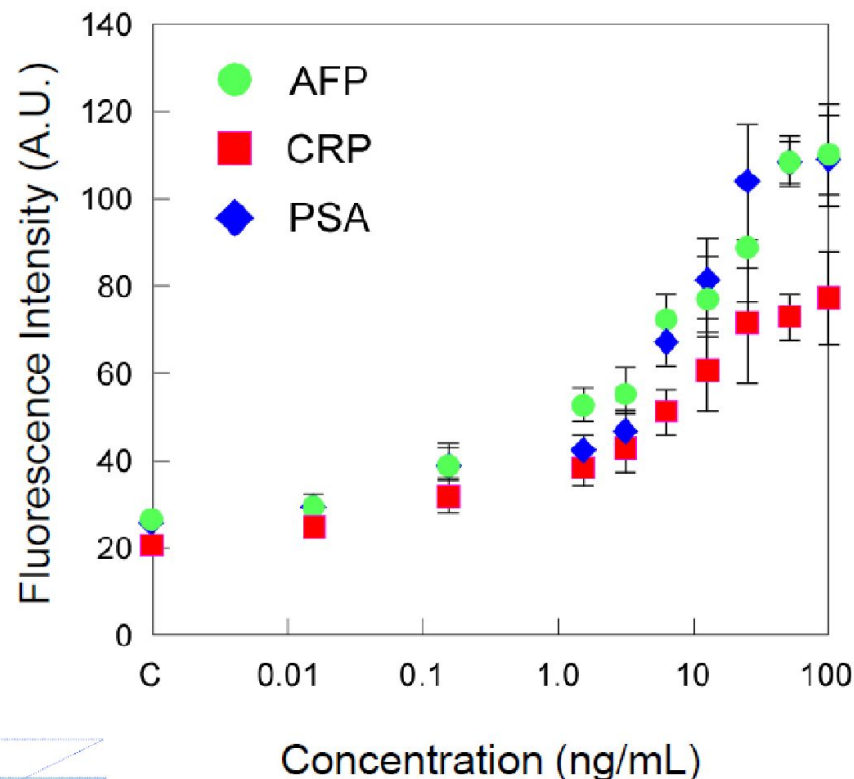

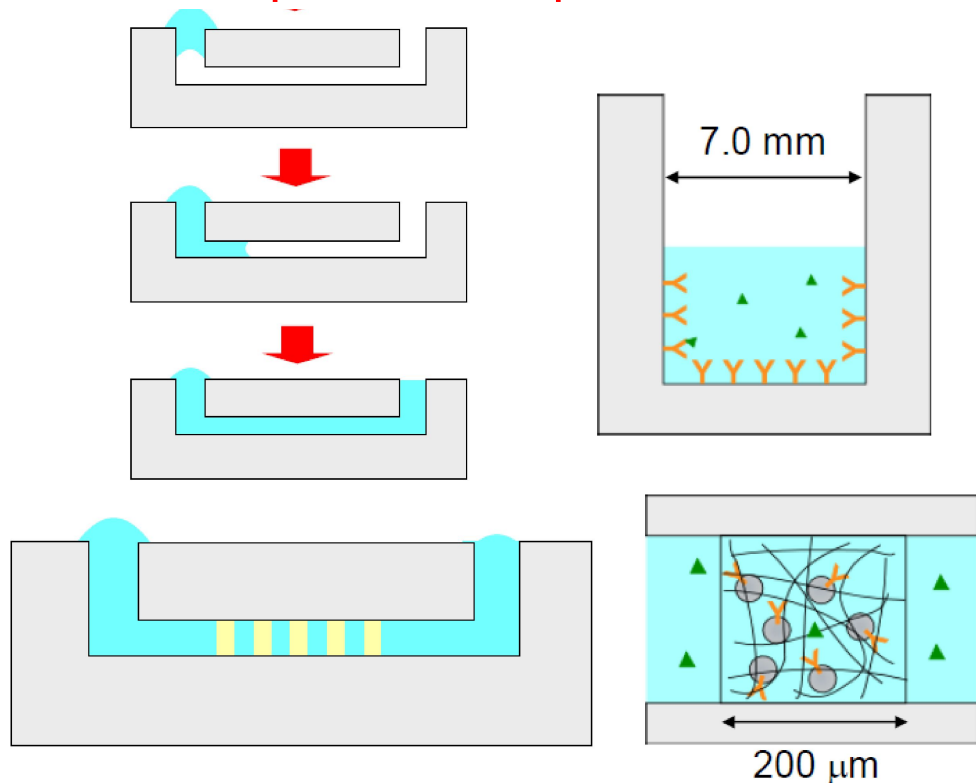

4. Repeat for other nucleotides

5. Build array until it is 25 nucleotides long

With 25 nucleotides in a sequence, there are 4^{25} (equal to 10^{15}) different combinations that can be made with this process. However, with a final chip size of 1.28 cm², there is only enough space for about 320,000 squares with different sequences.

Заключение Conclusion

- МЭМС и НЭМС представляют собой обширное семейство портативных приборов, датчиков и устройств. **Wide variety of portable devices.**
- Основным материалом НЭМС является кремний. **Material of choice for MEMS is Si.**
- Технологии НЭМС разработаны на базе технологий полупроводниковой электроники. **MEMS technology is taken from electronics**
- Уровень технологии НЭМС обеспечивает массовое производство надежных приборов и устройств различного назначения. **NEMS technology allows mass production.**
- Основными областями применения НЭМС являются биология и медицина, системы безопасности, системы связи и навигации, электроника и фотоника. **Major application areas are biology, medicine, safety systems, navigation, communications electronics photonics**

World smallest car

World's smallest car sitting on a coin. The car is 4.8mm long and runs on a 0.67mm electric motor.

World smallest guitar

A 10 μm long Si guitar (same size as a single cell) with six strings, each ~ 50 nm (100 atoms) wide. (Cornell University)
