Эрозии при ревматоидном артрите встречаются у 1 из 10 пациентов с ревматоидным артритом, при этом развиваются в сроки менее чем 6 месяцев от дебюта заболевания. Чаще всего эрозии обнаруживаются на локтевой стороне, дистальной трети локтевой кости под сухожилием локтевого разгибателя запястья.

Выпот в локтевом суставе. При исследовании 50 локтевых суставов у пациентов с ревматоидным артритом выпот в плечелоктевом суставе был выявлен у 17 пациентов с клинически «здоровыми» суставами, в ямке локтевого отростка у 23 пациентов с клинически «здоровыми» локтевыми суставами. 1-выпот, 2-капсула

УЗ исследование обладает значительно большей чувствительностью в выявлении выпота, в сравнении с рентгенографией. 1 - выпот, 2 - капсула.

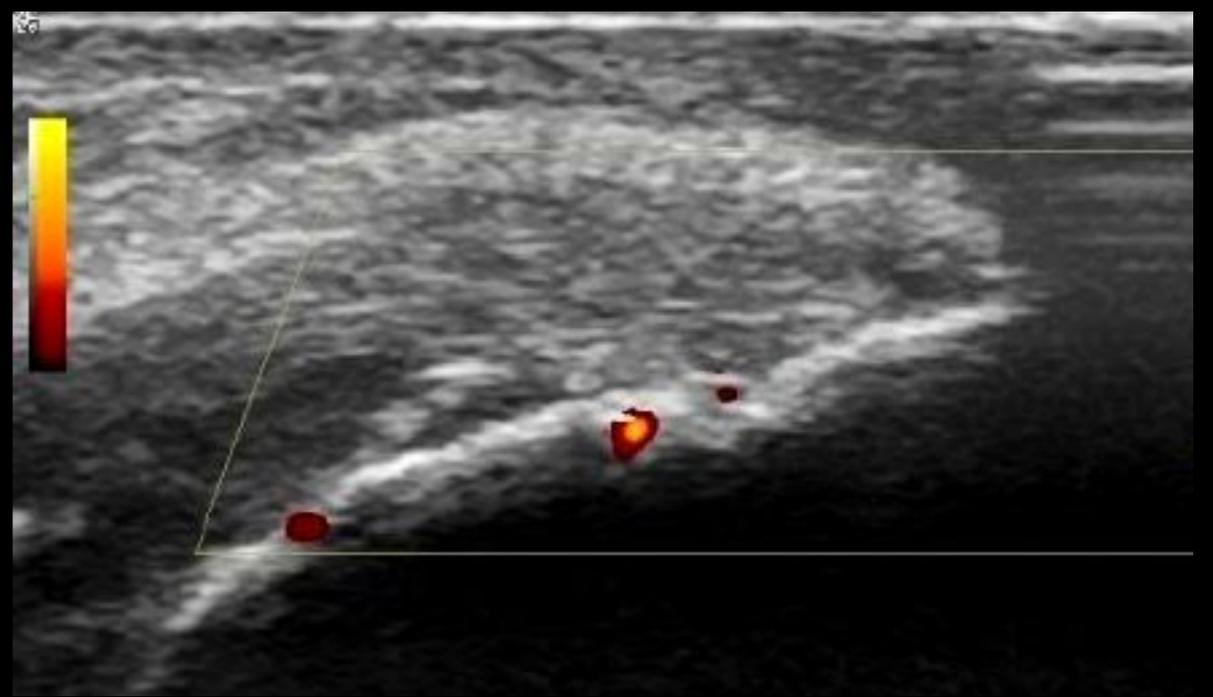

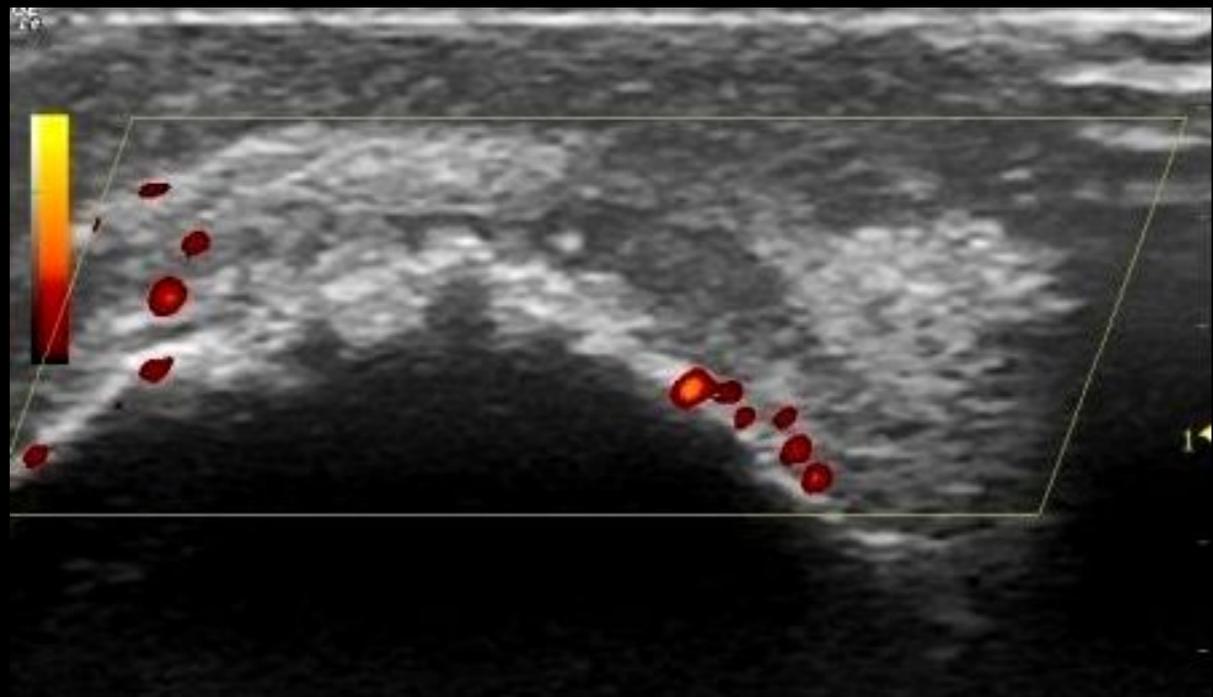

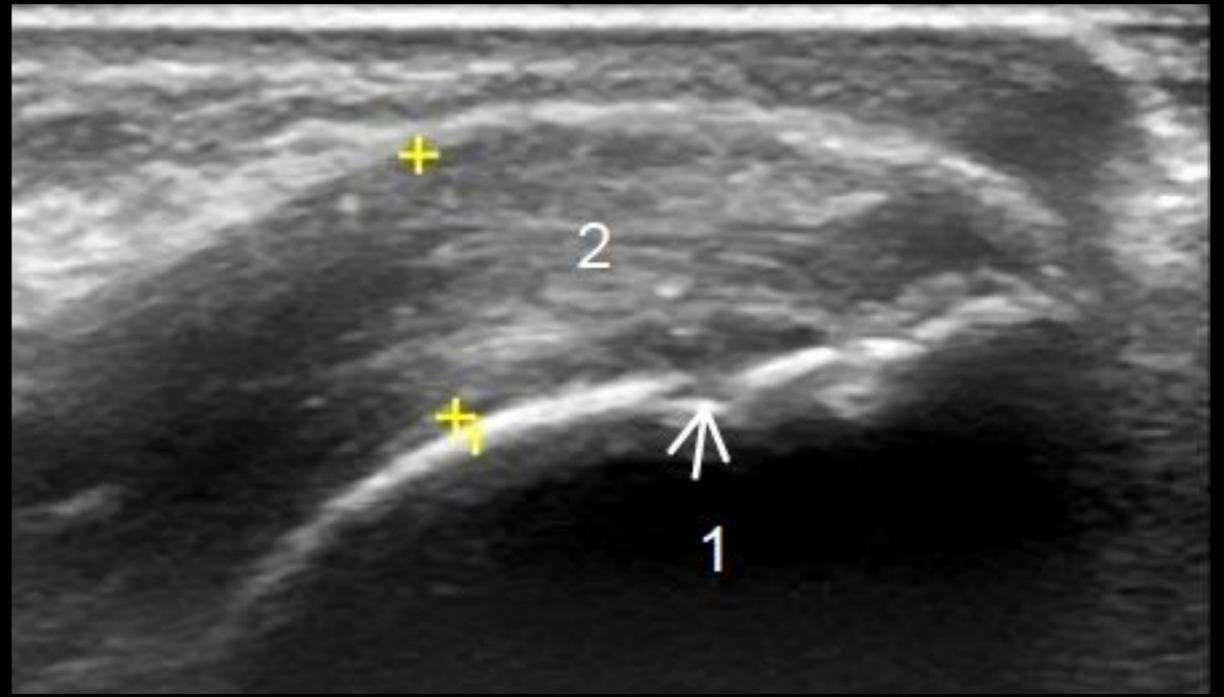

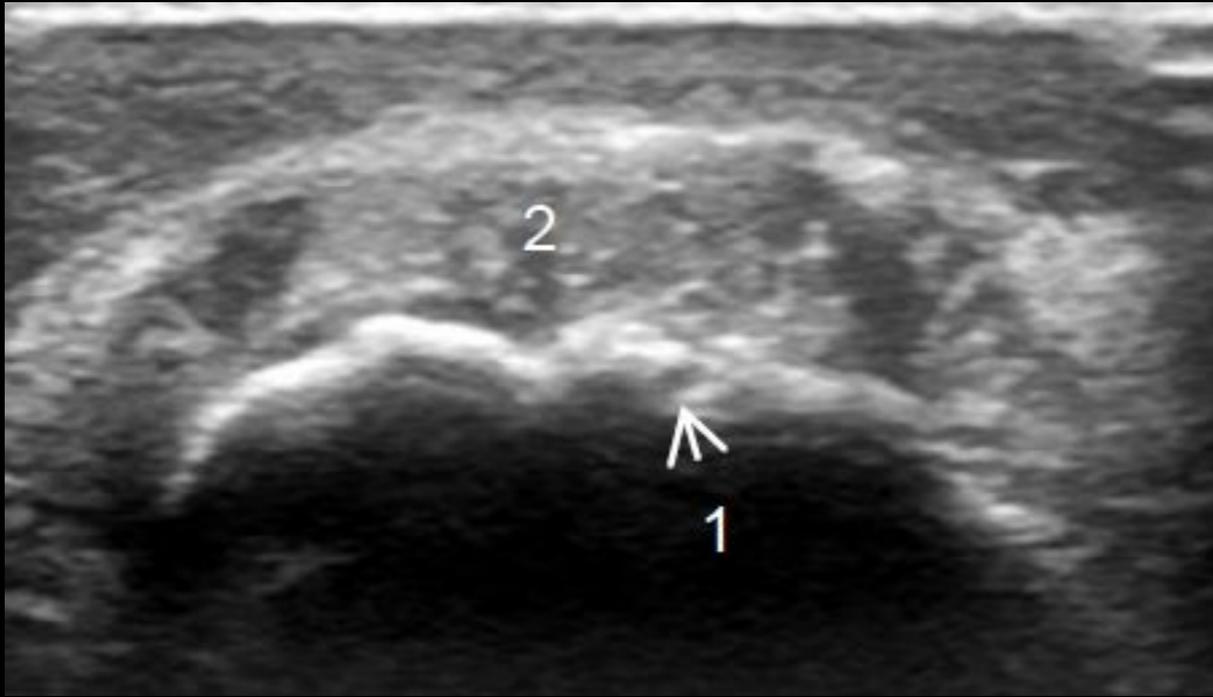

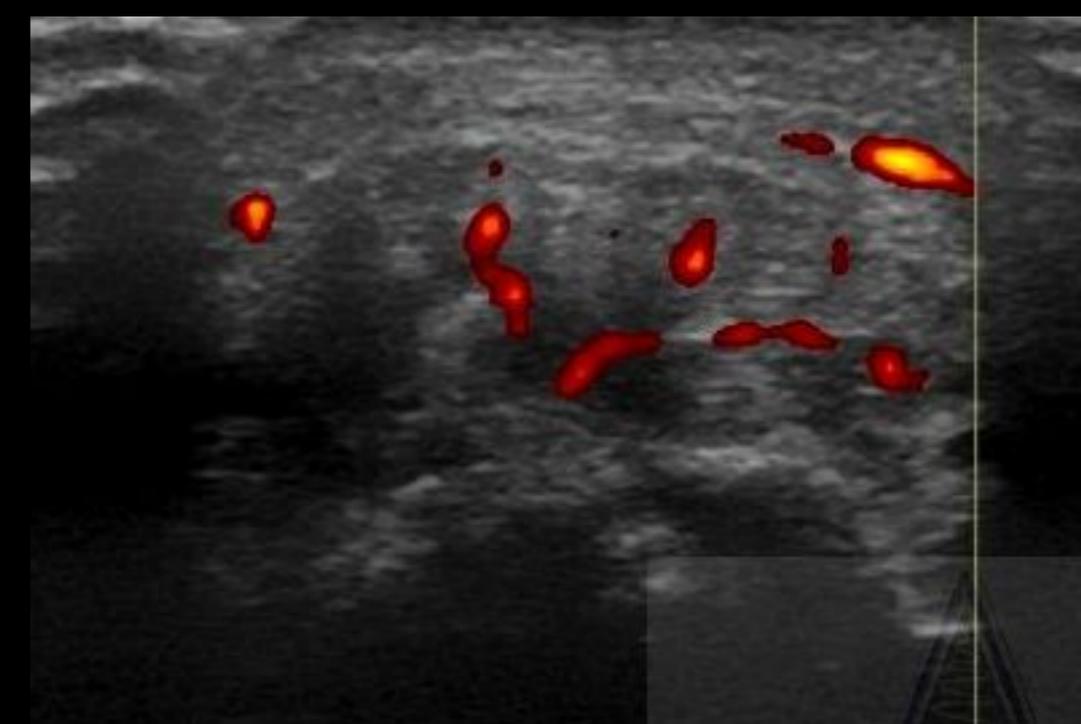

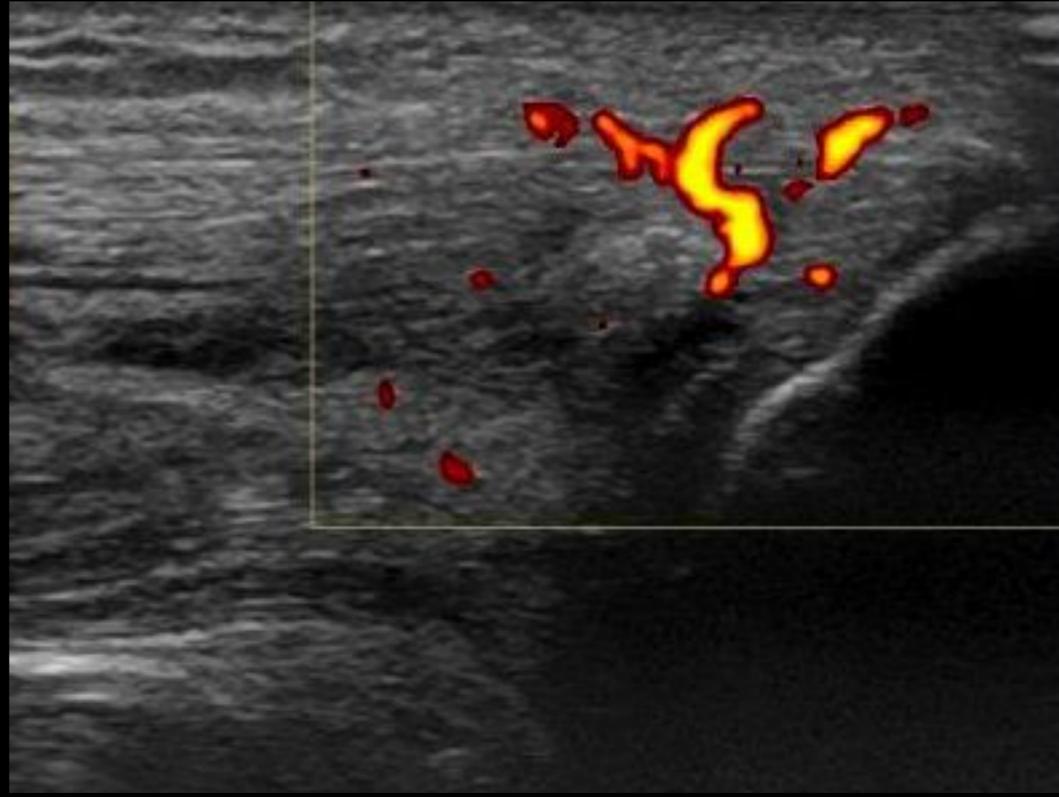

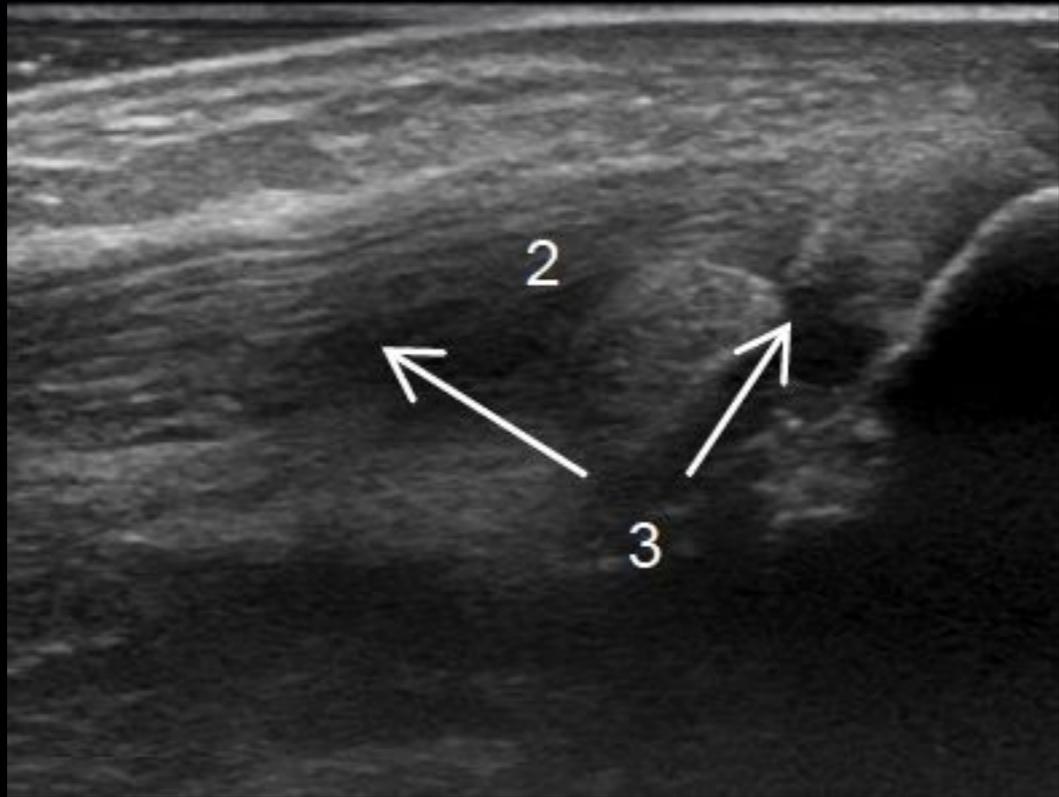

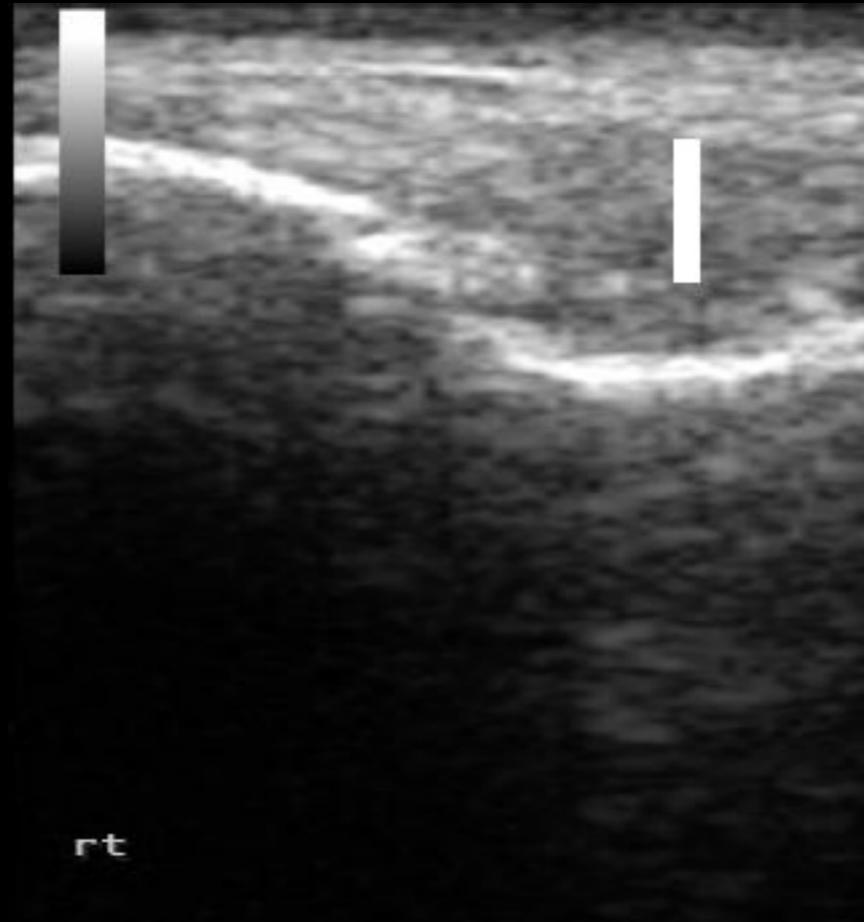

Бурсит локтевой суставной сумки, требуется очень аккуратное исследование с минимальной компрессией сумки, с тем, чтобы не вызвать сдавления мягких тканей и исчезновения скопления жидкости

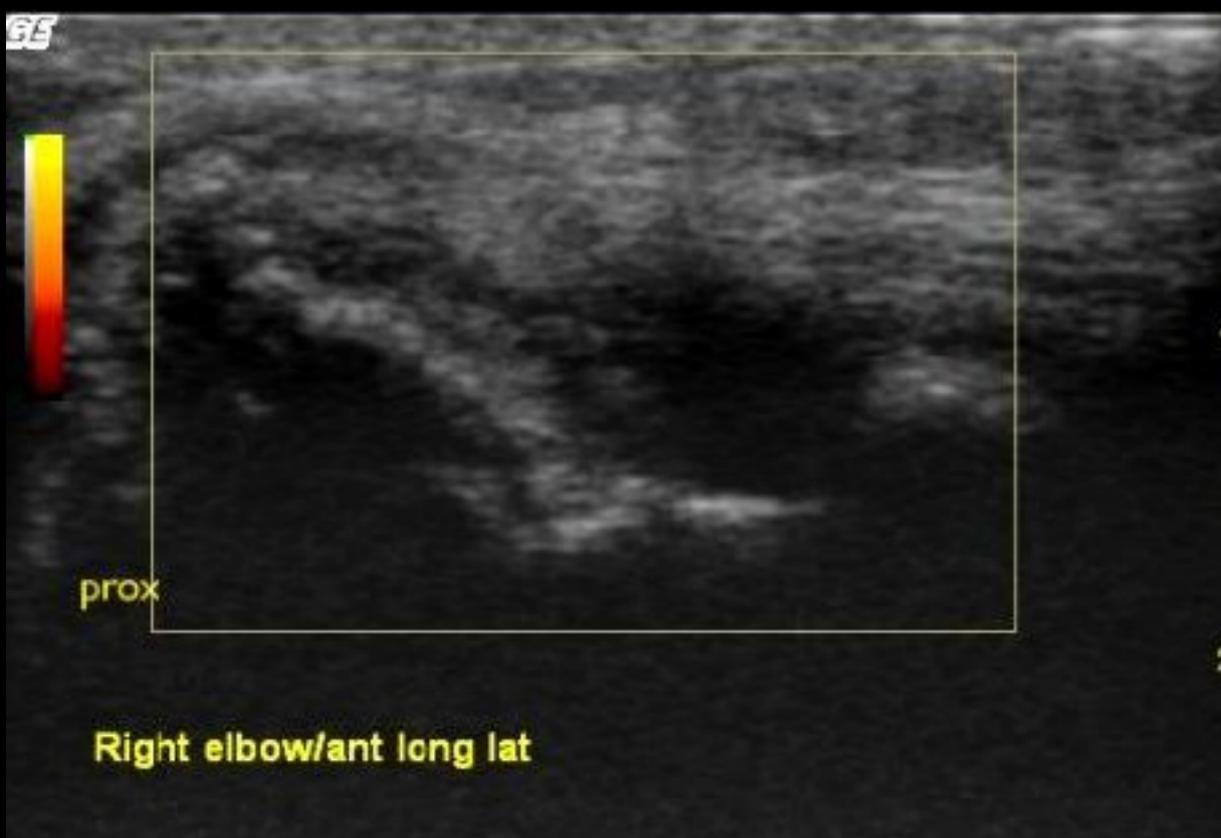

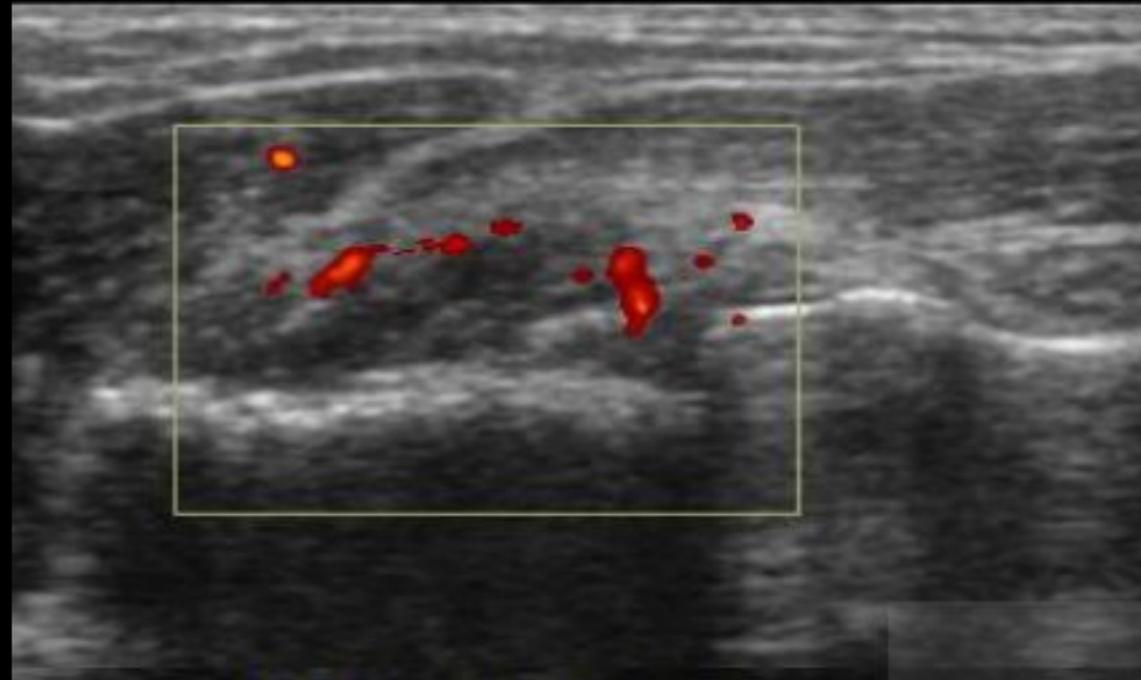

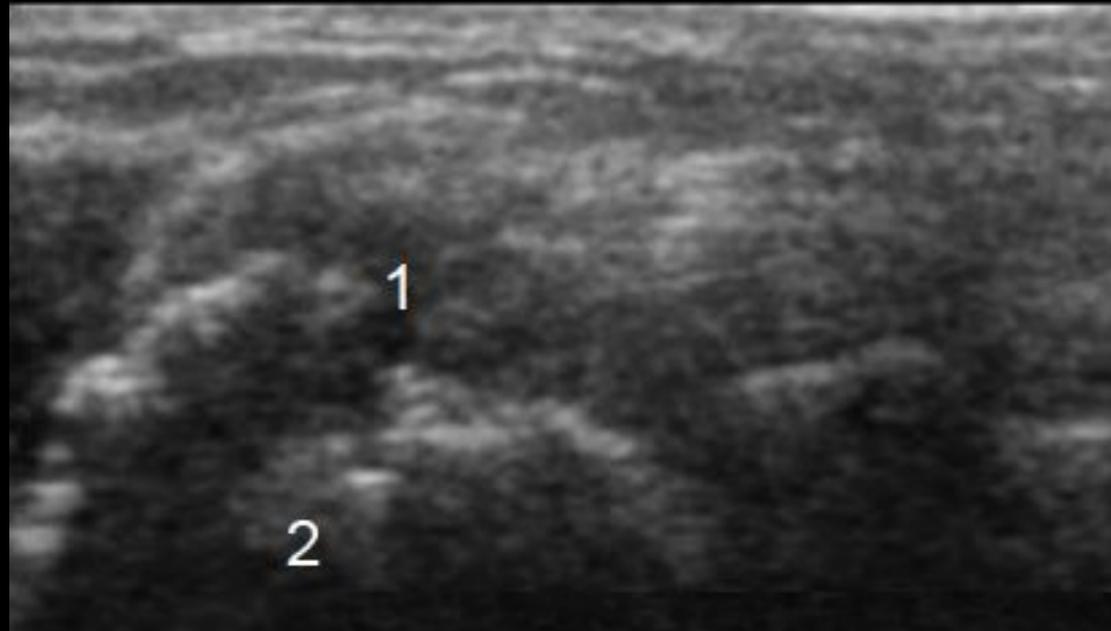

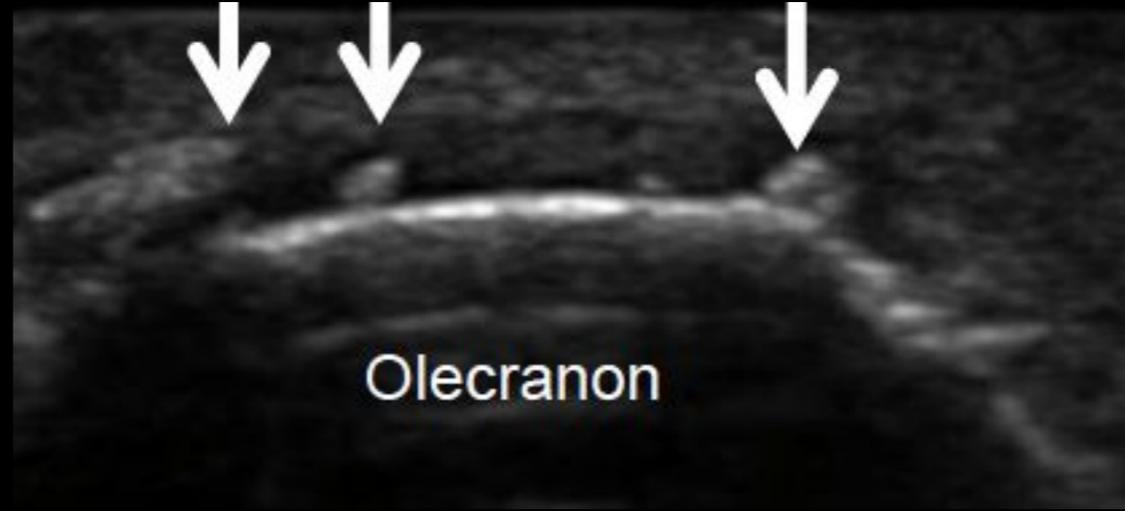

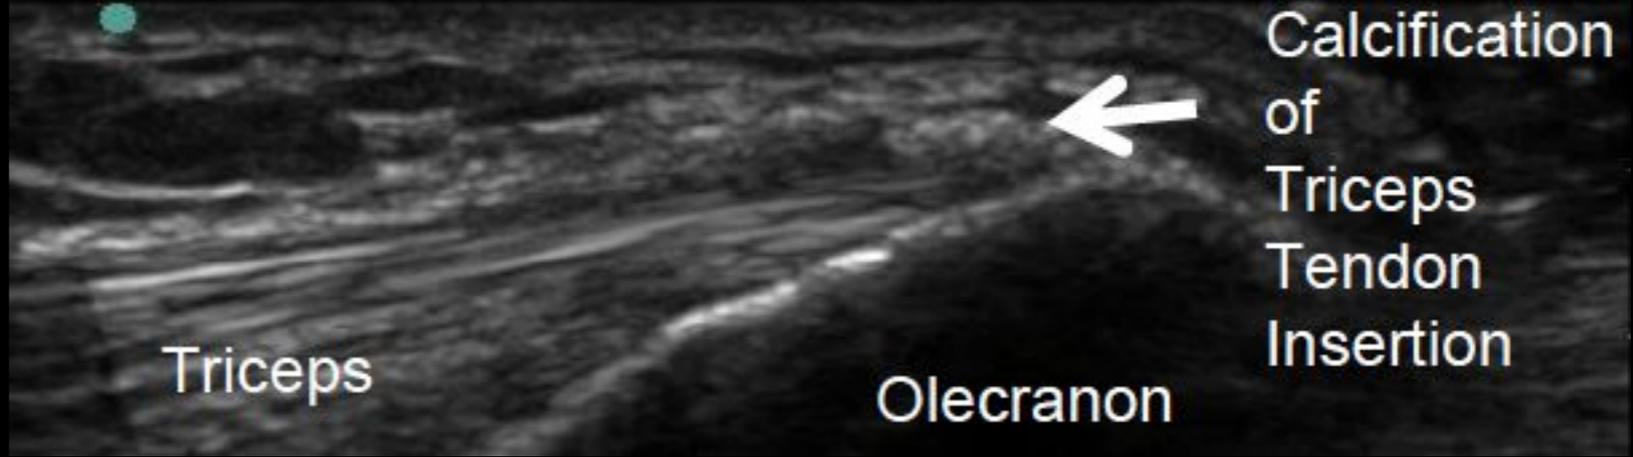

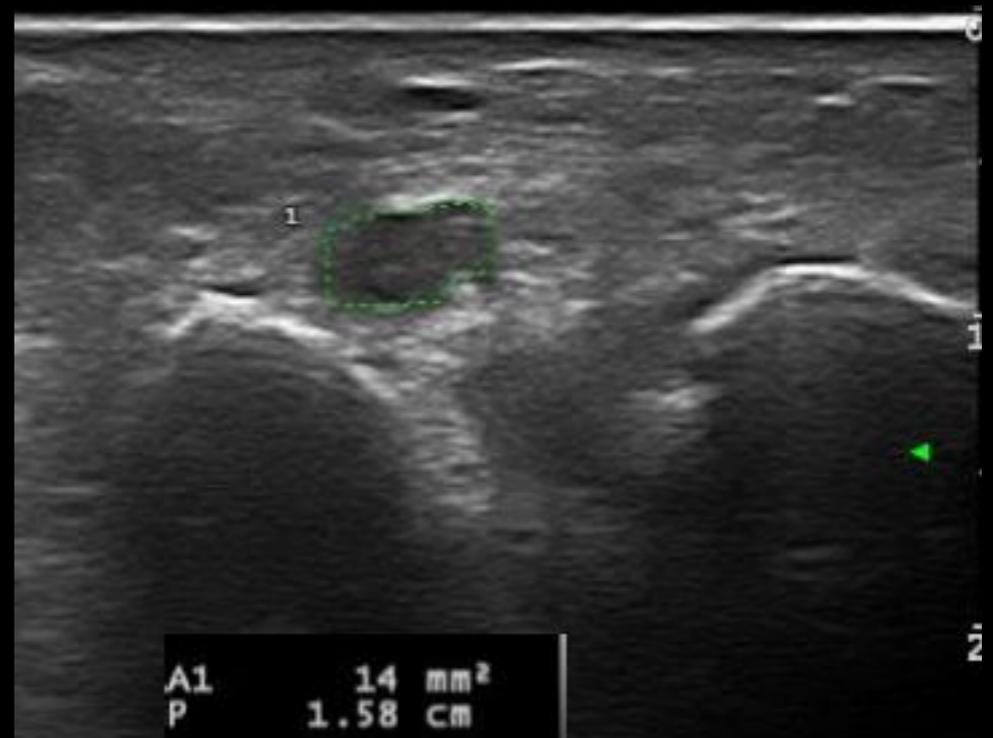

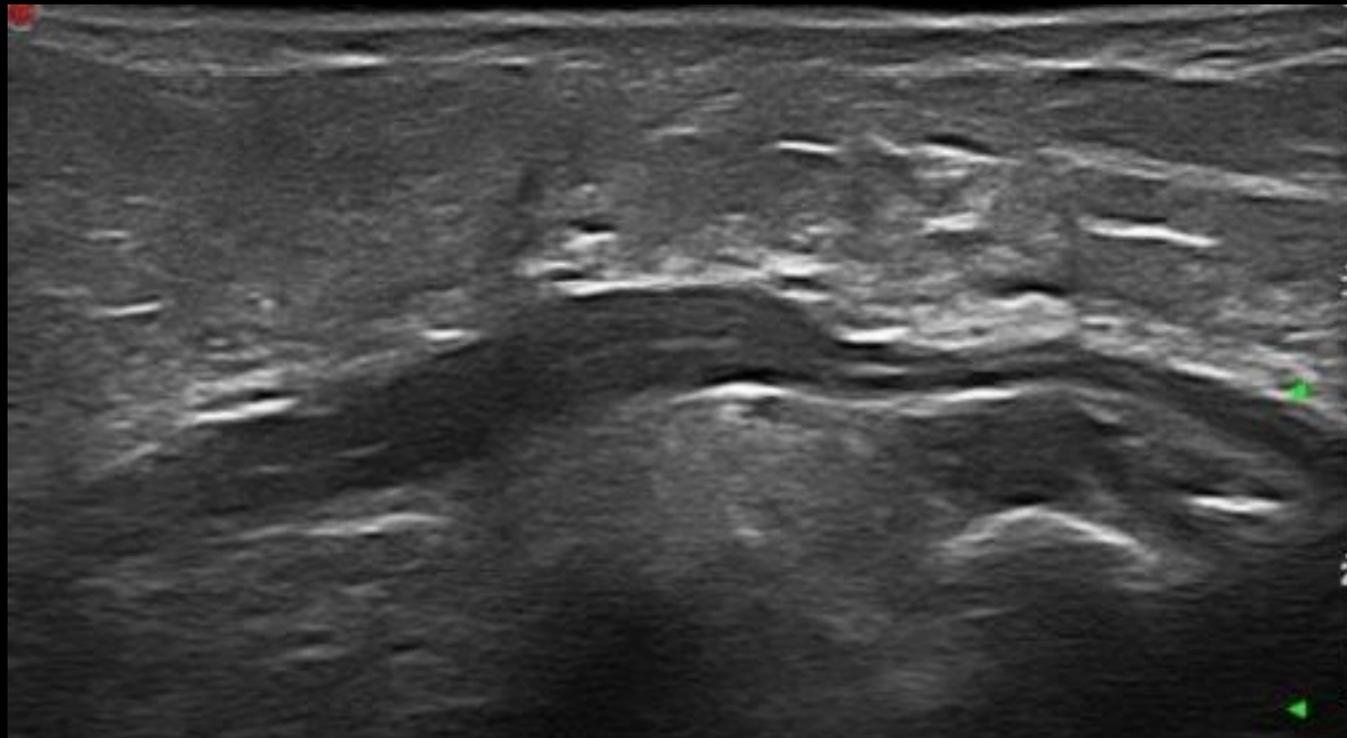

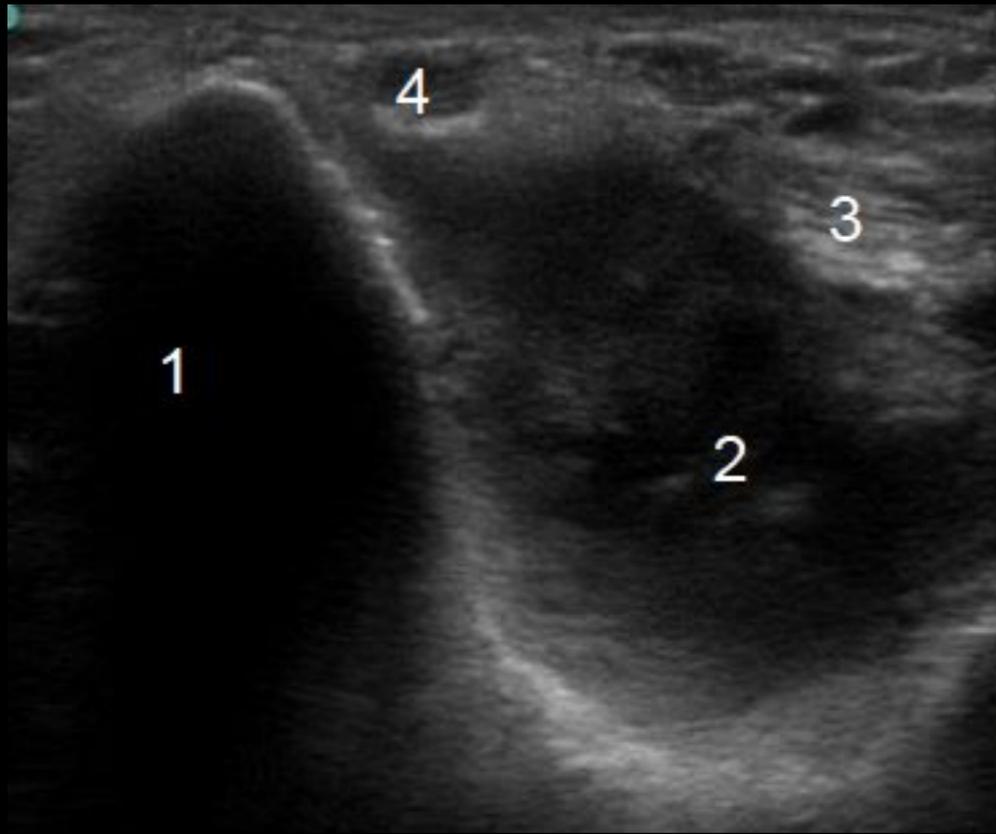

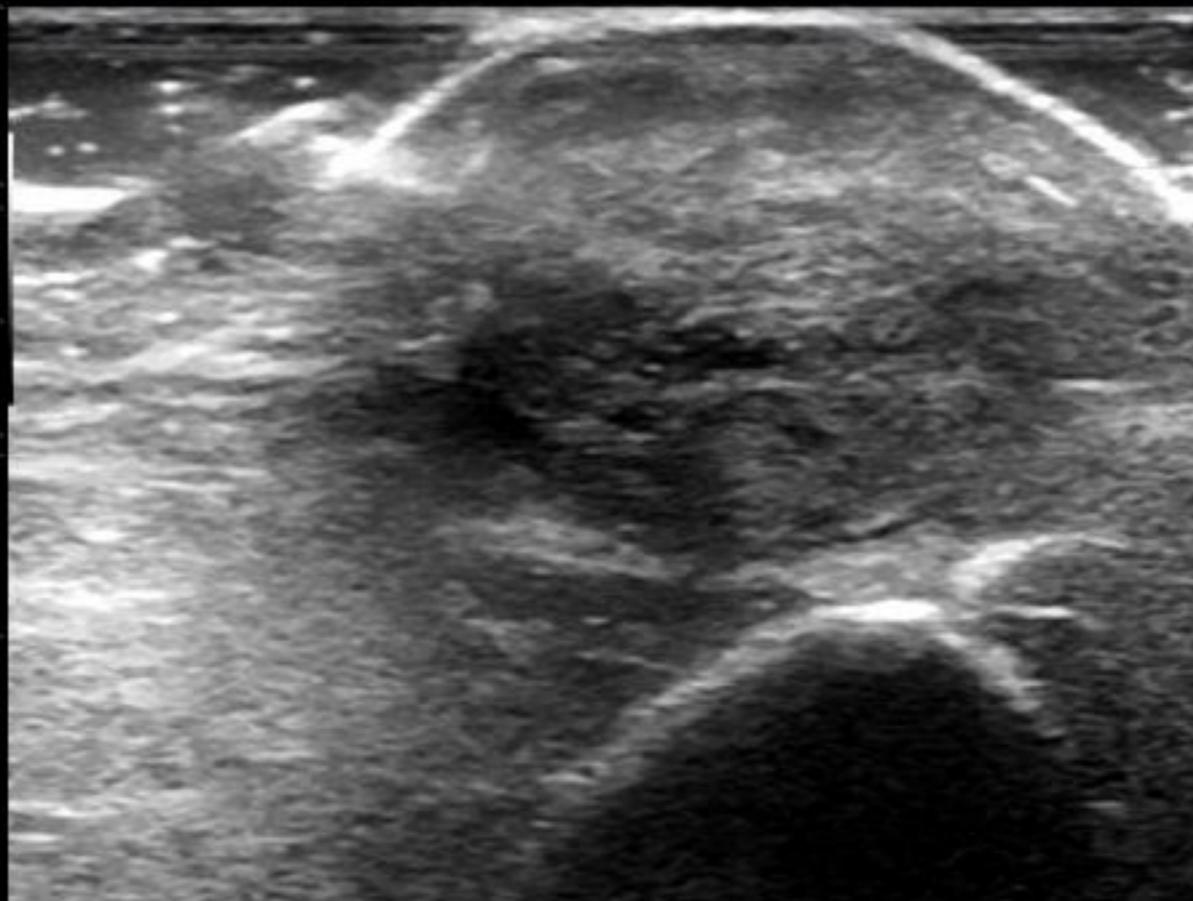

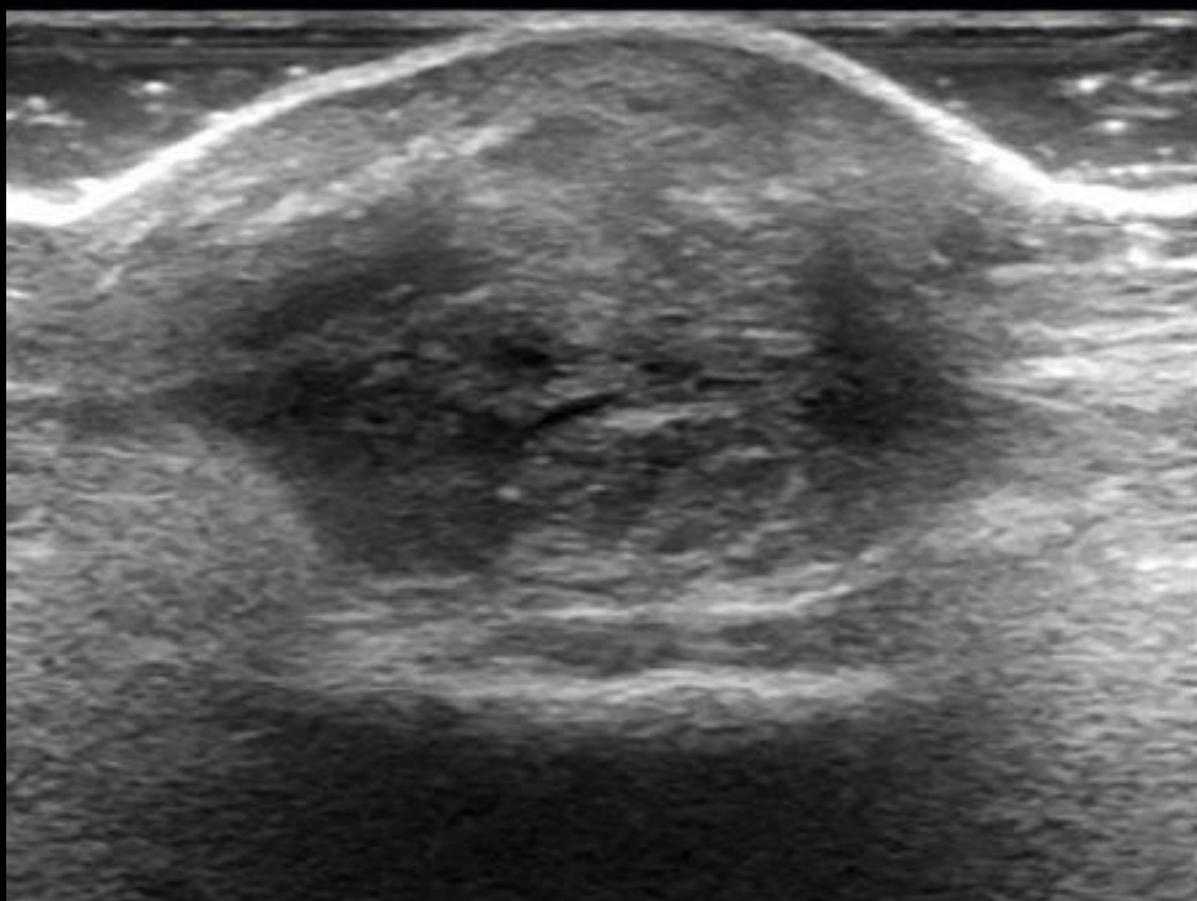

Ревматоидные узелки, похожи на подагрические тофусы, но отличаются от них за счет более четко определяемых границ, а так же по наличию центральной анэхогенной области некроза в своей структуре.
